

Low-altitude economy scenario strategy

Where should an internet or technology platform enter first?

RECOMMENDATION

Start with one constrained instant-delivery route and an asset-light digital services layer. Use licensed partners for aircraft, flight operations, and local permissions.

Base case: six scenarios, five criteria, four sensitivity profiles

Operations are scaling; local execution remains decisive

What the evidence supports

- The operating base is large enough for route-level commercial tests.
- Logistics, inspection, governance, medical rescue, tourism, and transport are recognized application areas.
- Digital coordination and risk data can become shared infrastructure.

What the evidence does not prove

- National growth does not establish city-level unit economics.
- A registered aircraft count does not equal commercial demand.
- Permissions, insurance, weather, landing sites, and public acceptance remain route-specific.

The platform advantage sits above the aircraft layer

The decision lens assumes a platform with users, merchants, maps, cloud, AI, payments, dispatch, and operations teams.

Delivery and digital services lead the base case

Weighted score: demand 20%, platform fit 25%, commercialization 20%, regulatory feasibility 20%, data and network effects 15%.

Advance
Instant delivery
Digital infrastructure and services

Partner selectively
Industrial inspection
Urban governance and medical logistics

Monitor
Tourism and passenger mobility

Use two entry wedges, not one large market bet

Wedge 1: one constrained delivery route

Customer problem

Ground delivery is slow, costly, or unreliable on a repeatable route.

Platform advantage

Existing orders, merchants, payments, maps, dispatch, and customer service.

Initial boundary

Fixed endpoints, defined weather and payload limits, licensed operator, and ground fallback.

Decision metrics

Cost per completed order, on-time rate, incident rate, route utilization, and repeat use.

Wedge 2: one operator workflow

Customer problem

Operators manage route, risk, dispatch, evidence, or insurance data across disconnected systems.

Platform advantage

Cloud, AI, mapping, identity, payment, workflow, and data integration.

Initial boundary

One licensed operator, one service station, and one workflow with clear users.

Decision metrics

Processing time, manual steps removed, data completeness, operator adoption, and willingness to pay.

Shared rule

Do not scale because the category is growing. Scale only after a route or workflow produces repeatable demand, safe operations, and an economic advantage over the current alternative.

A 90-day pilot should answer four decision questions

The first two priorities remain stable across four profiles

Strategy profile	1st	2nd	3rd
Base case	Instant delivery	Digital services	Industrial inspection*
Growth platform	Instant delivery	Digital services	Urban governance
Compliance first	Instant delivery	Digital services	Industrial inspection
Asset light	Instant delivery	Digital services	Urban governance

* Industrial inspection ties with urban governance in the base-case score; the table uses the reproducible row order.

Risk that can stop the pilot

No executable permission path; unclear safety responsibility; no credible ground fallback; or required insurance cannot be obtained.

Risk that can stop scaling

Low route utilization; weak willingness to pay; high manual operating load; or unit economics that do not improve with density.

Evidence needed next

City-level permission map, route demand, weather interruption rate, partner operating data, insurance terms, and a ground-delivery cost baseline.

Method, limitations, and sources

Method

Six scenarios are scored from 1 to 5 on demand, platform fit, commercialization, regulatory feasibility, and data/network effects. The weighted score supports comparison; it is not a market forecast, probability, or return estimate.

Limitations

Company operating figures are self-reported. Rules vary by city and route. The model does not estimate market size, cash flow, aircraft economics, or safety certification. A real investment decision requires route-level legal, operational, and financial diligence.
